Subject: Potomac River Generating Station (PRGS) VISSIM Analysis Results

Executive Summary

This memorandum presents the findings of a microsimulation (VISSIM) traffic analysis for the proposed redevelopment of the Potomac River Generating Station (PRGS) site. The PRGS site is located in the Old Town North (OTN) area of the City of Alexandria. Figure 1 identifies the regional site location and Figure 2 identifies the location of the site within the OTN area. The proposed development site is currently occupied by the Potomac River Generating Station, which is no longer in operation. It is bounded by Slaters Lane to the north, E Abingdon Drive and a PEPCO sub-station to the west, Norfolk Southern Corporation right-of-way to the south, and the Potomac River to the east.

The proposed development will include redeveloping the existing, unused power station site into a mixed-use development consisting of six (6) development blocks and an existing pumphouse identified for potential renovation and reuse. A total of up to 2.5 million square feet gross square feet (GSF) of development is proposed, with a mix of office, arts, retail, residential, and hotel uses proposed throughout the site. The exact program for each development block will be determined as part of future Development Special Use Permits (DSUPs). For the purposes of this analysis, a proposed program was assumed based on a split of 60% of GSF assigned to commercial uses and 40% of GSF assigned to residential uses, consistent with the development program assumed in the PRGS Coordinated Development District (CDD) Multimodal Transportation Study (MTS) and reflecting the most conservative development option. In terms of the analysis, this 60%/40% split between commercial and residential uses represent the most conservative vehicular trip generation scenario within the range of possible uses across the entire site. Commercial uses typically generate more vehicular trips compared to residential uses; therefore, the vehicular trip generation for the PRGS development may be lower if a higher residential split is ultimately proposed as part of the future DSUPs. Furthermore, it was assumed that existing traffic would remain on the network in its current travel patterns and no regional cut-through trips, particularly along the GW Memorial Parkway, were re-routed with the addition of the PRGS site. As a result, this analysis reflects a higher than anticipated number of vehicular trips regardless of the development scenario for the PRGS site and vehicular traffic anticipated on the GW Memorial Parkway.

The purpose of this memorandum is to present the findings of microsimulation (VISSIM) analysis that evaluate numerous conceptual alternatives for the intersections of Slaters Lane and Bashford Lane with the GW Memorial Parkway aimed at ameliorating the traffic impacts to vehicular modes generated by the proposed site, with the goal of identifying preferred alternatives which will be further studied as part of the Feasibility Study described in the project's Coordinated Development

District (CDD) Condition 37. Additionally, any modifications to the GW Memorial Parkway itself would be coordinated with the National Park Service (NPS).

VISSIM is a vehicular-focused software and the metrics used to evaluate each alternative focus on the optimization of vehicular operations, rather than evaluating the positive and/or negative impacts to non-auto modes. It is important that each potential improvement weigh both the findings of this analysis and non-auto considerations to ensure that improvements are implemented from a multimodal standpoint.

Previous stages of this effort included a Multimodal Transportation Study (MTS) for the PRGS CDD, which was completed in April 2022. The MTS used macroscopic (Synchro) traffic analysis to determine mitigations and presented additional alternative improvements to be studied in future efforts. In response to the findings and recommendations from the MTS, the City requested that this VISSIM analysis include additional improvements beyond those presented in the MTS. The mitigations proposed in the MTS were used as baseline improvements for the VISSIM analysis presented in this memorandum. In addition to those baseline mitigations, this effort analyzed the operational benefits of the recommendations in the MTS, improvements requested by the City in response to the MTS, and improvements identified by Gorove Slade. The results of the VISSIM analysis confirmed the need for the mitigations identified in the MTS and quantified the operational benefits, from a vehicular standpoint, of the additional improvements the City had asked be studied. The comprehensive analyses and comparisons of alternatives identified by the City and Gorove Slade are detailed in this memorandum.

The following findings of this study are discussed in more depth in the memorandum that follows:

- Conceptual Alternatives Development:
 - Twelve (12) conceptual alternatives were analyzed as part of this memorandum. The conceptual alternatives include baseline improvements identified as part of the PRGS CDD MTS, improvements identified by the City for exploration, and additional improvements identified throughout the conceptual alternative development and analysis. The improvements proposed were limited to signing and striping, signal infrastructure improvements, and traffic operation modifications, and were analyzed assuming they can be implemented within the existing curb-to-curb limits of the GW Memorial Parkway.
 - Each conceptual alternative was analyzed with and without the potential new E-W Connection to GW Memorial Parkway and E/W Abingdon Drive.
 - Preferred alternatives were identified based on the results of this analysis.
- Vehicular Volumes:
 - All of the analyzed conceptual alternatives were able to process more vehicles through the study area network than under 2022 Existing conditions, and most were able to process more vehicles than under 2033 Background conditions without the PRGS redevelopment.
 - The goal of this analysis was to identify improvements that increased the number of processed vehicles compared to 2033 Background conditions and process a comparable percentage of the expected volumes compared to 2033 Background conditions. In the AM peak hour, 97% of vehicles were processed under 2033 Background conditions. In the PM peak hour, 91% of vehicles were processed. The above percentages were then established as the vehicular throughput targets for 2033 Future analyses, with the goal of identifying improvements that would allow for a comparable or improved percentage of vehicles to be processed. These targets were met or exceeded in three (3) alternatives in the AM peak hour (Alternatives 6, 7B, and 9) and six (6) alternatives in the PM peak hour (MTS Baseline and Alternatives 2, 5B, 6, 7B, and 9).
 - Modifications to traffic signal cycle length and phasing schemes were biggest contributors to the increase vehicles processed.

- Vehicular Delays:
 - The lowest overall network-wide vehicular delays were shown in Alternatives 5A, 6, 7A, 7B, and 9 in the AM peak hour and in Alternatives 7B, 8, and 9 in the PM peak hour.
- Simulated Vehicular Travel Times:
 - The travel time results for most alternatives are comparable to that reported for 2033 Background conditions during the AM and PM peak hours.
- Maximum Queue Length:
 - The maximum queue lengths for most approaches of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the AM and PM peak hours.
 - The maximum queue lengths for most approaches of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the AM and PM peak hours.
- Potential New East-West Connection:
 - When the conceptual alternatives were re-analyzed with the inclusion of the potential new E-W connection, it was found that the new connection may provide some minor advantages to vehicular throughput, delay, travel times, and queuing, particularly in the AM peak hour, with slight disadvantages in the PM peak hour.
 - The addition of a potential new E-W Connection allowed several alternatives to meet or exceed the percentage of vehicles processed under the 2033 Background scenario, as compared to the same alternatives without the connection. However, the overall increases were minimal: approximately 4% in the AM peak hour and 2% in the PM peak hour. Furthermore, improvements were not the same across the study area or between peak hours. In the AM peak hour, the greatest improvement in vehicle throughput was observed northbound on the GW Memorial Parkway, whereas minimal improvement was observed for eastbound vehicles on Slaters Lane. In the PM peak hour, minor improvements to vehicular throughput were observed southbound on the GW Memorial Parkway with no notable improvements elsewhere in the network.
 - Total vehicular delay at study intersections decreased in the AM peak hour with the introduction of the new E-W Connection. However, the results for the PM peak hour were mixed. In roughly half of the analyzed alternatives, the total delay increased in the PM peak hour once the connection was added, with reductions in delays in the remaining alternatives.
 - The travel time results generally mirror the vehicular delay results. In the AM peak hour, there was an overall reduction in average travel times with the addition of the new connection. In the PM peak hour, there was an overall reduction in average travel times in roughly half of the analyzed alternatives, with increases in travel times in the remaining alternatives.
 - Maximum queue lengths results were mixed, with queue lengths generally decreasing in roughly half of the analyzed alternatives in both the AM and PM peak hours. The new E-W connection adds flexibility in route choice for drivers entering/exiting the PRGS site; however, reductions in queue lengths for one approach is offset by an increase in queue lengths for another approach where the vehicles have shifted.
- Overall Findings and Conclusions:
 - From a vehicular standpoint, the results indicate that Alternatives 6, 7B, and 9 would result in the greatest operational improvements by prioritizing the number of vehicles processed by the analysis network, while minimizing impacts to vehicular delay, queues, and travel times. Each of these preferred alternatives are able to process at least the same percentage of vehicles as was processed in the 2033 Background scenario during both the AM and PM peak hours. Each preferred alternative also performed better than the other analyzed alternatives

in at least one of the other MOEs of vehicular delays, vehicular travel times, and vehicular queues. It is important that each potential improvement weigh both the findings of this analysis and non-auto considerations to ensure that improvements are implemented from a multimodal standpoint.

- This memorandum recommends that the preferred alternatives identified as part of this analysis (Alternatives 6, 7B, and 9) be studied further in the future as the PRGS site develops. The underlying assumptions for the trip generation for the PRGS redevelopment were based on a conservative development program, which is subject to change as part of future DSUPs and may result in fewer vehicular trips, and pre-COVID-19 pandemic data, and likely are not fully representative of current or future driver behavior and traveler decisions (e.g., remote work, dispersion of trip patterns across peak periods). Additionally, the improvements identified based on this analysis would not be implemented until the end of Phase 2 of the PRGS redevelopment, at which point assumptions could be refined with respect to the proposed development program and shifts in commuting patterns in the study area. The site trip generation calculations were based on the most conservative (60% commercial/40% residential) development option for the PRGS site with the highest number of new vehicular trips. Anticipated trip generation is subject to change as development uses are refined in future DSUPs.
- When the preferred alternatives are re-analyzed with the inclusion of the potential new E-W connection, it was found that the new connection may provide some minor advantages to vehicular throughput, delay, travel times, and queuing, particularly in the AM peak hour, with slight disadvantages in the PM peak hour. The potential new E-W Connection will be further studied once future DSUPs are submitted in Phase 2. As part of this future study, the analysis should weigh the advantages and disadvantages of the new connection for non-vehicular modes against that for vehicles.

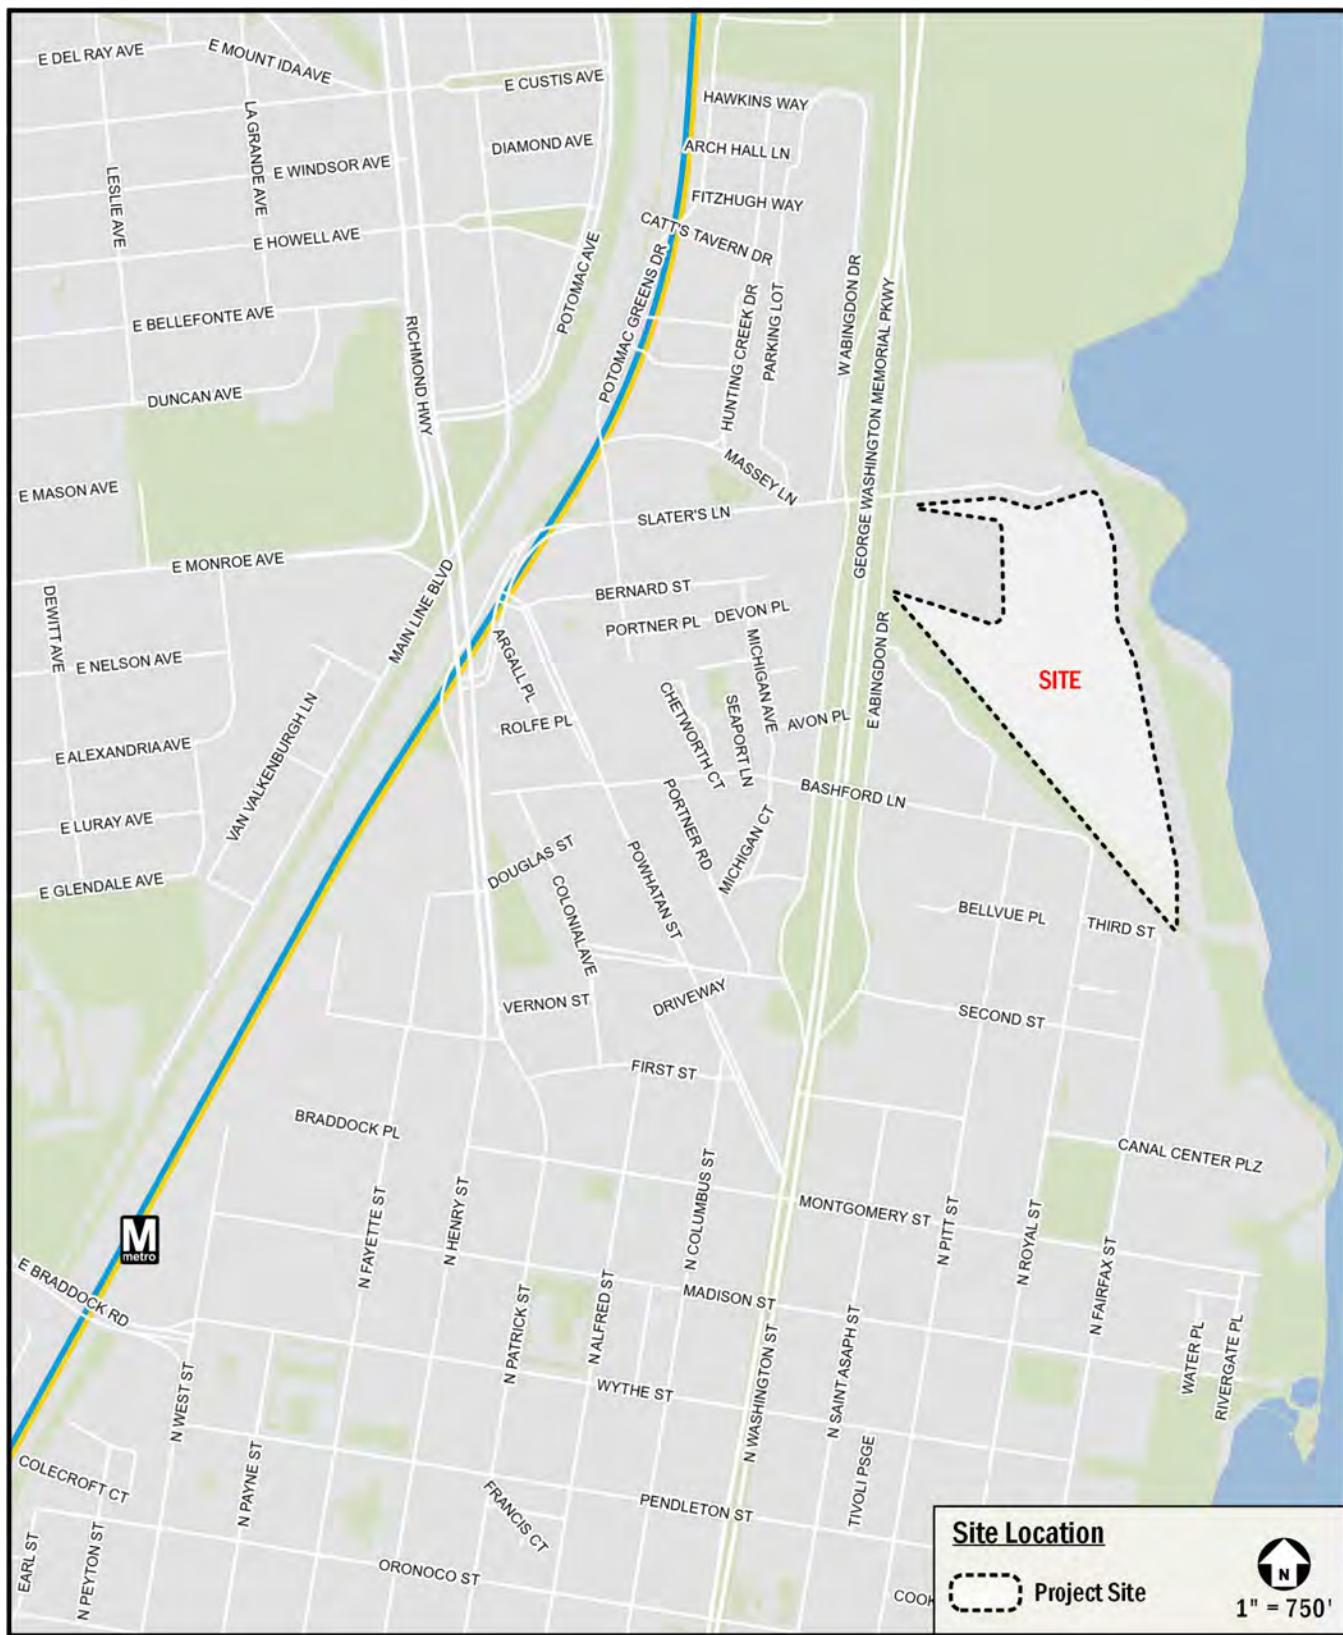

Figure 2: Site Location

Scope of VISSIM Analysis

The scope of the microsimulation analysis was discussed with and agreed to with the City of Alexandria. The methodology of the microsimulation analysis follows City of Alexandria and industry-accepted standards. The analysis scope is provided in the Technical Attachments.

VISSIM Analysis Scenarios

Several scenarios were included in this alternatives analysis. These were developed based on the results of the PRGS CDD MTS, input from the City of Alexandria, and additional scenarios identified based on the results of this VISSIM analysis. The following scenarios were analyzed for both the AM and PM peak hours:

- 2022 Existing Conditions
- 2033 Future without Development (2033 Background)
- 2033 Future with Development (2033 Future)
- 2033 Future Mitigated with Development (MTS Baseline)
 - 11 Alternative Mitigation Scenarios (detailed in Table 2)
- 2033 Future Mitigated with Development and a New E-W Connection (MTS Baseline)
 - 11 Alternative Mitigation Scenarios with a New E-W Connection

Study Area

The following intersections were identified for inclusion in the VISSIM network, as shown in Figure 3 and Figure 4. Additional intersections were included in the network for metering purposes and results will not be reported for these locations.

1. Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive
2. Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive
3. New East-West Connection and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive (Potential)

These intersections were selected for analysis because they are the most likely to have potential impacts or require changes to traffic operations to accommodate the PRGS Redevelopment. Given the unique challenges and geometry at the agreed upon study intersections, VISSIM was selected as the software for this study. Compared to typical deterministic analysis tools, such as Synchro, VISSIM is a microsimulation modelling tool that measures the performance of individual vehicles as they travel through the network while accounting for the influence of other vehicles, transit, and pedestrians.

Traffic Volume Assumptions

Traffic demand forecasting for all analyzed scenarios will be based on the assumptions included in the PRGS CDD MTS (dated April 7, 2022), including inherent regional growth rates, background developments, and any planned network improvements.

The PRGS CDD MTS was based on the preferred development option proposed by the applicant, which includes a total of up to 2.5 million GSF of development with a mix of office, arts, retail, residential, and hotel uses. The exact program for each development block will be determined as part of future DSUPs. For the purposes of this analysis, a proposed program was assumed based on a split of 60% of GSF assigned to commercial uses and 40% of GSF assigned to residential uses, consistent with the development program assumed in the PRGS CDD MTS and reflecting the most conservative development option. In terms of the analysis, this 60%/40% split between commercial and residential uses represent the most conservative vehicular trip generation scenario within the range of possible uses across the entire site. Commercial uses typically generate more vehicular trips compared to residential uses; therefore, the vehicular trip generation for the PRGS development may be lower if a higher residential split is ultimately proposed as part of the future DSUPs. Furthermore, it was assumed that existing traffic

would remain on the network in its current travel patterns and no regional cut-through trips, particularly along the GW Memorial Parkway, were re-routed with the addition of the PRGS site. As a result, this analysis reflects a higher than anticipated number of vehicular trips regardless of the development scenario for the PRGS site and vehicular traffic anticipated on the GW Memorial Parkway.

The 2022 Existing Conditions peak hour traffic volumes are shown on Figure 5. The 2033 Background Conditions peak hour traffic volumes are shown on Figure 6. The 2033 Future Conditions peak hour traffic volumes are shown on Figure 7. Re-routed volumes due to the potential new E-W connection are detailed in a later section of this memorandum.

Measures of Effectiveness

The Measures of Effectiveness (MOEs) used to evaluate the VISSIM results include:

- **Vehicular Volumes:** This metric is used to help identify each alternative's ability to process volumes through the network, thus identifying issues relating to capacity.
- **Vehicular Delay:** This metric calculates the time spent by each vehicle in the network traveling below their desired speed.
- **Simulated Vehicular Travel Times:** This metric measures the time it takes a vehicle, on average, to traverse a given segment of the network.
- **Maximum Queue Length at study intersections:** This metric evaluates the maximum queue lengths observed on approaches to study intersections.

2022 Existing Analysis Results

Simulation Model Development and Existing Calibration

The existing VISSIM model was developed by Gorove Slade using existing signal timings and phasing information provided by the City of Alexandria, existing geometry and lane configuration observed in the field, and turning movement count data collected in May 2022. The approved calibration memorandum is included in the Technical Attachments.

Model calibration is the process of performing adjustments to the model to better simulate local driving behavior and operational performance. The calibration process typically compares field data (volumes, speed, travel time, queue length, etc.) to the simulation output so that the model represents actual traffic conditions in the study area. A model that is appropriately calibrated improves the model's ability to assess the future conditions of the study area. The calibration criteria were scoped and approved by the City. All reasonable efforts were made to calibrate the VISSIM models to the calibration criteria and targets.

Travel time measurements were collected in the field along both directions of GW Memorial Parkway, E Abingdon Drive, and W Abingdon Drive, between Slaters Lane and Bashford Lane. Maximum queue lengths were observed simultaneously with traffic count data collection.

Some model parameters were adjusted to reflect actual network performance and driver behaviors. The models were run with adjusted parameters and the outputs were examined against field measurements and observations.

The VISSIM modeling calibration used in this analysis met the calibration acceptance targets in nearly all cases, as shown in Table 1 below. The calibrated existing models were used as a base for all future year scenarios included in this memorandum.

Table 1: VISSIM Modeling Calibration Criteria and Results

Calibration Criterion ¹	Calibration Target ^{1,2}	Results	
		AM Peak	PM Peak
Modeled Link Volume (vehicles per hour)			
Within ± 100 vph for < 700 vph			
Within ± 15% for 700 vph to 2,700 vph	100% of cases	100%	95.8%
Within ± 400 vph for > 2,700 vph			
Within ± 5% of sum of all link counts	± 5%	- 1%	+ 9%
Modeled Travel Time (seconds)			
Within ± 15% of Observed Travel Times	100% of cases	100%	100%
Simulated Queue Length			
Within ± 30% of observed queue lengths	100% of cases	91.7%	91.7%

2. VDOT TOSAM (2020) identifies calibration target of 85%

2033 Future VISSIM Analysis (Without the Potential E-W Connection)

Development of Conceptual Alternatives

A Multimodal Transportation Study (MTS) for the PRGS CDD was completed in April 2022. The recommended mitigations identified as part of that effort were used as the basis for conceptual alternative development. The mitigations recommended in that report included the following:

- Modifications to signal phasing and signal timings at the intersections of Slaters Lane with the GW Memorial Parkway and E/W Abingdon Drive. The signal phasing scheme proposed in the MTS is displayed in Figure 8.
- Restriping of approaches at the intersections of Slaters Lane with the GW Memorial Parkway and E/W Abingdon Drive to consolidate turning movements through the clustered intersection. The existing and proposed striping at the Slaters Lane intersections are shown in Figure 9 and Figure 10, respectively.
- Restriping of approaches at the intersections of Bashford Lane with the GW Memorial Parkway and W Abingdon Drive to consolidate turning movements through the clustered intersection. The existing and proposed striping at the Bashford Lane intersections are shown in Figure 11 and Figure 12, respectively.

In response to the PRGS CDD MTS, the City requested that this VISSIM analysis explore additional improvements to address the unique challenges at the intersections at Slaters Lane and Bashford Lane with the GW Memorial Parkway, W Abingdon Drive, and E Abingdon Drive.

Additional alternatives were identified by Gorove Slade throughout the conceptual alternative development and analysis. The improvements were aimed at addressing issues observed in the scoped set of alternative VISSIM models. A list of all considered improvements is provided below, including those proposed by the City in the scoping document and those additional improvements identified by Gorove Slade. The improvements proposed here are limited to signing and striping, signal infrastructure improvements, and traffic operation modifications and were analyzed assuming they can be implemented within the existing curb-to-curb limits the GW Memorial Parkway. The mitigations identified in the PRGS CDD MTS were considered baseline mitigations and are common across all alternatives; as such, those improvements are not included in the list below.

In addition to the descriptions provided in the list below, each improvement is presented visually in Figure 13 and Figure 14.

Scoped Improvements (Requested by City of Alexandria)

- A. Restripe the southbound approach of the intersection of Slaters Lane and W Abingdon Drive to provide a southbound left-turn lane
 - Implementation of a southbound left-turn lane on this approach would make implementation of a southbound right-turn turn, which is proposed in the MTS, infeasible within the existing curb-to-curb. Therefore, alternatives which included the southbound left-turn improvement did not include a southbound right-turn lane on the same approach.
 - A northbound right-turn lane on the northbound approach of the intersection of Slaters Lane and E Abingdon Drive was also proposed in the VISSIM scoping document and comments from the City. However, the analysis team deemed this improvement infeasible due to limited cycle lengths and because the northbound left turning movement is projected to be prohibited in the AM peak hour and fewer than 10 vehicles in the PM peak hour.
- B. Modify traffic signal phasing at Slaters Lane to provide an exclusive phase for the southbound left-turning traffic from W Abingdon Drive. Vehicles making the southbound left would be able to continue through the intersections with GW Memorial Parkway and E Abingdon Drive during the same phase.

- This modification is reflected in the Exclusive Left Turn Proposed AM/PM Peak Phasing scheme included in Figure 15.
- C. Restripe the segment of W Abingdon Drive between Slaters Lane and the diverge point on the GW Memorial Parkway to provide two lanes of storage along its full length.
- D. Modify traffic signal timings at Slaters Lane and Bashford Lane to increase the overall cycle length and adjust traffic phase split times and offsets to align with the increased cycle lengths.

Additional Improvements

- E. Modify traffic signal timings at Slaters Lane and Bashford Lane to minimize pedestrian wait times by limiting split times for northbound and southbound vehicular movements to 60 seconds.
- F. Modify traffic signal timings at Slaters Lane and Bashford Lane to optimize minimum green times on eastbound and westbound phases and reduce conflict between turning vehicles and pedestrians.
 - Under existing conditions, pedestrians traveling eastbound or westbound on Slaters Lane, are given a walk sign at the same time as the westbound vehicles. This results in conflicts between westbound vehicles turning left onto W Abingdon Drive or GW Memorial Parkway and pedestrians crossing those respective streets. Therefore, this improvement proposes linking these pedestrian movements to eastbound vehicular movements. In this scenario, right-turning vehicle conflicts are still present, but these are considered safer than left-turning conflicts. The resulting phase configuration is such that eastbound and westbound pedestrian could cross W Abingdon Drive and GW Memorial Parkway (at Slaters Lane) with phase 4 and cross E Abingdon Drive with phases 3 or 4.

Summary of Alternatives

Each of the alternatives evaluated as part of this VISSIM analysis combined multiple improvement measures from the lists in the previous section and Figure 13 and Figure 14. All alternatives included the mitigations proposed in the MTS as a baseline, except for in cases where an additional improvement was incompatible with a baseline MTS mitigation. A breakdown of the improvements included in each alternative is provided in Table 2 below.

Table 2: Alternative Matrix

Alternative	MTS Mitigation Measures				Additional Improvements (See Figures 11 & 12)					
	Add'l Bashford Ln Receiving Lane	SBR Turn Lane on W Abingdon Dr	Turn Restrictions as Slaters Ln & Bashford Ln	Phasing Modifications	A	B	C	D	E	F

2033 Future VISSIM Analysis Results (Without the Potential E-W Connection)

A total of 12 conceptual alternatives were analyzed using microsimulation (VISSIM) software to determine the preferred combination of strategies improve operations at the GW Memorial Parkway. The Measures of Effectiveness (MOEs) used to evaluate the VISSIM results were based on the goals of the project, along with standard transportation engineering metrics, and were scoped and approved by the City. The conceptual alternatives were compared based on each of the following MOEs:

- **Vehicular Volumes:** This metric is used to help identify each alternative's ability to process volumes through the network, thus identifying issues relating to capacity.
- **Vehicular Delay:** This metric calculates the time spent by each vehicle in the network traveling below their desired speed.
- **Simulated Vehicular Travel Times:** This metric measures the time it takes a vehicle, on average, to traverse a given segment of the network.
- **Maximum queue Lengths:** This metric evaluates the maximum queue lengths observed on approaches to study intersections.

Detailed MOE tables for each alternative are provided in the Technical Attachments. VISSIM is a vehicular-focused software and the MOEs used to evaluate each alternative focus on the optimization of vehicular operations, rather than evaluating the positive and/or negative impacts to non-auto modes. It is important that each potential improvement weigh both the findings of this analysis and non-auto considerations to ensure that improvements are implemented from a multimodal standpoint.

Vehicular Volumes

Vehicular volume results are used to help identify each alternatives' ability to process vehicular volumes on a macro and micro level. These results are expressed as the number of vehicles processed into network. Individual link vehicular volume throughput at each study intersection is provided in the Technical Attachments.

AM Peak Hour

The number of vehicles processed at network entry points system-wide are presented for all alternatives are summarized in Table 3 for the AM peak hour. The percentage of vehicles processed compared to the input vehicles for the peak hour is also included for each alternative.

All of the analyzed conceptual alternatives (which include 2033 Background traffic volumes plus those generated by the PRGS site) were able to process more vehicles through the study area network than under 2022 Existing conditions, and most were able to process more vehicles than under 2033 Background conditions without the PRGS redevelopment. The goal of this analysis was to identify improvements that increased the number of processed vehicles compared to 2033 Background conditions and process a comparable percentage of the expected volumes compared to 2033 Background conditions. For the AM peak hour, the 2033 Background benchmark was 97% of vehicles processed. The following alternatives met or exceeded this benchmark in the AM peak hour:

- 2033 Future Alternative 6
- 2033 Future Alternative 7B
- 2033 Future Alternative 9

PM Peak Hour

The number of vehicles processed at network entry points system-wide are presented for all alternatives are summarized in Table 3 for the PM peak hour. The percentage of vehicles processed compared to the input vehicles for the peak hour is also included for each alternative.

All of the analyzed conceptual alternatives were able to process more vehicles through the study area network than under 2022 Existing conditions, and most were able to process more vehicles than under 2033 Background conditions without the PRGS redevelopment. The goal of this analysis was to identify improvements that increased the number of processed vehicles compared to 2033 Background conditions and process a comparable percentage of the expected volumes compared to 2033 Background conditions. For the PM peak hour, the 2033 Background benchmark was 91% of vehicles processed. The following alternatives met or exceeded this benchmark in the PM peak hour:

- 2033 Future Mitigated (MTS Baseline)
- 2033 Future Alternative 2
- 2033 Future Alternative 5B
- 2033 Future Alternative 6
- 2033 Future Alternative 7B
- 2033 Future Alternative 9

Table 3: Number of Vehicles Processed into Network

Alternative	AM Peak Hour		PM Peak Hour	
	Vehicles Processed (veh/hr)	Vehicles Processed as a Percentage of Input Vehicles (%)	Vehicles Processed (veh/hr)	Vehicles Processed as a Percentage of Input Vehicles (%)
2022 Existing	4,742	100%	5,336	100%
2033 Background	4,969	97%	5,345	91%
2033 Future	5,012	86%	5,990	89%
2033 Future Mitigated (MTS Baseline)	5,133	88%	6,082	91%
2033 Future Alternative 1	5,167	89%	5,995	89%
2033 Future Alternative 2	5,131	88%	6,238	93%
2033 Future Alternative 3	5,614	96%	6,069	90%
2033 Future Alternative 4	5,172	89%	6,008	89%
2033 Future Alternative 5A	5,416	93%	5,994	89%
2033 Future Alternative 5B	5,612	96%	6,118	91%
2033 Future Alternative 6	5,624	97%	6,208	92%
2033 Future Alternative 7A	5,408	93%	6,004	89%
2033 Future Alternative 7B	5,621	97%	6,215	93%
2033 Future Alternative 8	5,052	87%	6,056	90%
2033 Future Alternative 9	5,671	97%	6,198	92%

Vehicular Delays

Simulated vehicular delay results show the difference between the actual vehicle travel time due to stops at a signalized intersection (control delay) and is measured in seconds of delay per vehicle.

It is important to note that VISSIM is a microscopic analysis rather than a macroscopic analysis. The recommended improvements are in place to address targeted issues at specific locations, as well as increase the vehicular throughput of the overall network. Due to the increased number of vehicles being processed in the network compared to 2033 Background conditions, there may be locations where delays are higher than that seen under 2022 Existing and/or 2033 Background conditions for some locations.

AM Peak Hour

The average approach delay for each alternative is shown in Table 4 for the AM peak hour for the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection. The average approach delay for each alternative is shown in Table 5 for the AM peak hour for the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection. Table 6 shows the vehicular delays for the overall intersection for each study intersection.

The vehicular delay results show that Alternates 5A and 7A had the lowest delay compared to other alternatives. However, it is important to note that approximately 93% vehicles were processed by each alternative (see Table 3). The next lowest delays were in Alternatives 6, 7B, and 9 which processed approximately 97% of vehicles each. The vehicular delays for Alternatives 5A and 7A do not account for those vehicles which were not processed into the network; therefore, report delays may be lower than expected.

PM Peak Hour

The average approach delay for each alternative is shown in Table 7 for the PM peak hour for the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection. The average approach delay for each alternative is shown in Table 8 for the AM peak hour for the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection. Table 9 shows the vehicular delays for the overall intersection for each study intersection.

The vehicular delay results show that Alternatives 7B, 8, and 9 had the lowest delay compared to other alternatives. However, it is important to note that approximately 93%, 90%, and 92% of vehicles were processed by each alternative, respectively (see Table 3). The vehicular delays for Alternatives 7B, 8, and 9 do not account for those vehicles which were not processed into the network; therefore, report delays may be lower than expected.

Simulated Vehicular Travel Times

Vehicular travel time is the amount of time it takes for a vehicle to travel from point A to point B. It is a direct reflection of motorist experience. Therefore, it is a critical and effective measure when evaluating and comparing the conceptual alternatives. The four (4) travel time segments that were analyzed as part of the analysis were (shown in Figure 16):

- Northbound GW Memorial Parkway north of Bashford Lane to north of Slaters Lane
- Southbound GW Memorial Parkway south of Slaters Lane to south of Bashford Lane
- Northbound E Abingdon Drive north of Bashford Lane to north of Slaters Lane
- Southbound W Abingdon Drive south of Slaters Lane to south of Bashford Lane

AM Peak Hour

Simulated travel time results for the four (4) vehicular travel time measurement segments that were analyzed using VISSIM in for each conceptual alternative are shown in Table 10 for the AM peak hour. The travel time results are reported in terms of the average travel time for each segment, as well as a volume-weighted average travel time across all four (4) segments for an overall comparison.

The travel time results for most alternatives are comparable to that reported for 2033 Background conditions during the AM peak hour. The travel time results show that Alternatives 5B and 7B had the lowest overall average travel time, considering all four (4) travel time segments, and were both lower than 2033 Background conditions and similar to 2022 Existing conditions.

PM Peak Hour

Simulated travel time results for the four (4) vehicular travel time measurement segments that were analyzed using VISSIM in for each conceptual alternative are shown in Table 11 for the PM peak hour. The travel time results are reported in terms of the average travel time for each segment, as well as a volume-weighted average travel time across all four (4) segments for an overall comparison.

The travel time results for most alternatives are comparable to that reported for 2033 Background conditions during the PM peak hour. The travel time results show that Alternative 2 performed had the lowest overall average travel time, considering all four (4) travel time segments, and was lower than 2033 Background conditions and similar to 2022 Existing conditions.

Maximum Queue Length

The maximum queue length is the maximum observed distance from the stop bar to the back of queue or to the next upstream study intersection.

AM Peak Hour

The average maximum queue length for five (5) simulation runs at each approach of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection is shown in Table 12 for the AM peak hour. The average maximum queue length for five (5) simulation runs at each approach of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection is shown in Table 13 for the AM peak hour.

The maximum queue lengths for all approaches of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the AM peak hour, with some exceptions. The greatest variability is observed on the southbound approach on W Abingdon Drive. Alternatives 1 and 5B show the highest maximum queue lengths (4,982 and 3,250 feet, respectively). The maximum queue length for this approach is approximately 2,000 feet under Alternatives 3, 4, 7B, and 9.

The maximum queue lengths for all approaches of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the AM peak hour, with some exceptions. The greatest variability is observed on the eastbound and westbound approach on Bashford Lane. Alternatives 3, 6 and 8 show the highest maximum queue lengths. For the eastbound approach, the maximum queue lengths observed under these three (3) alternatives ranged from 965 to 1,456 feet. For the westbound approach, the maximum queue lengths observed under these three (3) alternatives ranged 609 to 736 feet.

PM Peak Hour

The average maximum queue length for five (5) simulation runs at each approach of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection is shown in Table 14 for the PM peak hour. The average maximum queue length for five (5) simulation runs at each approach of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection is shown in Table 15 for the PM peak hour.

The maximum queue lengths for all approaches of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the PM peak hour, with some exceptions. The greatest variability is observed on the southbound approach on W Abingdon Drive and the eastbound approach on Slaters Lane.

- Alternative 5B shows the highest maximum queue length (4,378 feet) at the southbound approach on W Abingdon Drive. For comparison, the queue length for this approach is approximately 3,500 feet under Alternatives 3, 7B, and 9.
- The MTS Baseline alternative and Alternatives 2, 3, and 6 show the highest maximum queue length at the eastbound approach on Slaters Lane. The maximum queue length across these four (4) alternatives ranged from 1,586 to 1,950 feet.

The maximum queue lengths for all approaches of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the PM peak hour.

Preferred Alternatives

Based on the analysis results summarized in the previous section, there are several viable alternatives that could improve vehicular operations at the GW Memorial Parkway. Of the viable alternatives, three (3) alternatives are preferred and recommended for future study. Alternatives 6, 7B, and 9 each process levels of traffic comparable to that processed under 2033 Background conditions in the AM and PM peak hours, while minimizing impacts to vehicular delay, queues, and travel times. Each alternative performed better than other alternatives in at least vehicular delays, vehicular travel times, or maximum queue lengths.

VISSIM is a vehicular-focused software and the metrics used to evaluate each alternative focus on the optimization of vehicular operations, rather than evaluating the positive and/or negative impacts to non-auto modes. It is important that each potential improvement weigh both the findings of this analysis and non-auto considerations to ensure that improvements are implemented from a multimodal standpoint.

The improvements included in each preferred alternative are included below:

- **2033 Future Alternative 6:**
 - Additional eastbound receiving lane on Bashford Lane
 - Added southbound right-turn lane on W Abingdon Drive at Slaters Lane
 - Lane configuration modifications on Bashford Lane
 - Turn restrictions at the Slaters Lane and Bashford Lane intersections to consolidate turning movements
 - Phasing modifications at Slaters Lane (see Base Proposed Phasing schemes in Figure 15)
 - Extend two lanes of storage on W Abingdon Drive between Slaters Lane and GW Memorial Parkway
 - Modified cycle length of the Slaters Lane and Bashford Lane intersections
- **2033 Future Alternative 7B:**
 - Additional eastbound receiving lane on Bashford Lane
 - Lane configuration modifications on Bashford Lane
 - Turn restrictions at Slaters Lane and Bashford Lane intersections to consolidate turning movements
 - Phasing modifications at Slaters Lane (see Base Proposed Phasing schemes in Figure 15)
 - Southbound left-turn lane on W Abingdon Drive at Slaters Lane
 - Extend two lanes of storage on W Abingdon Drive between Slaters Lane and GW Memorial Parkway
 - Modified cycle length of the Slaters Lane and Bashford Lane intersections
- **2033 Future Alternative 9:**
 - Additional eastbound receiving lane on Bashford Lane
 - Lane configuration modifications on Bashford Lane
 - Turn restrictions at Slaters Lane and Bashford Lane intersections to consolidate turning movements
 - Phasing modifications at Slaters Lane (see Modified Proposed Phasing schemes in Figure 15)
 - Added southbound left-turn lane on W Abingdon Drive at Slaters Lane
 - Extend two lanes of storage on W Abingdon Drive between Slaters Lane and GW Memorial Parkway
 - Modified cycle length of the Slaters Lane and Bashford Lane intersections
 - Modified traffic signal timings at Slaters Lane and Bashford Lane to optimize eastbound and westbound movements and reduce conflict between turning vehicles and pedestrians (see Modified Proposed Phasing schemes in Figure 15)

2033 Future VISSIM Analysis (With the Potential E-W Connection)

As part of the VISSIM analysis, a potential new east-west connection was analyzed for all 2033 Future scenarios. The objective of this analysis was to determine whether implementation of the new connection would result in significant impacts, negative or positive, to vehicular operations compared to the same alternatives without the implementation of the new connection.

Analysis Assumptions

Geometric and Operations Assumptions

For purposes of this analysis, the potential new E-W Connection was assumed to tie into GW Memorial Parkway and E/W Abingdon Drive approximately where the current Norfolk Southern railroad tracks intersect with GW Memorial Parkway, consistent with what was assumed in the PRGS CDD MTS. Also consistent with the PRGS CDD MTS, the potential new connection was assumed to have one (1) lane in both directions. The southbound approach on W Abingdon Drive was assumed to have one (1) thru lane and one (1) shared thru-left lane. The northbound approach on E Abingdon Drive was assumed to have one (1) shared thru-left lane and one (1) shared thru-right lane. Similar to the operations at Slaters Lane and Bashford Lane, turning movements from GW Memorial Parkway onto the new connection would not be permitted. This potential connection would require the cooperation and coordination of NPS and other property owners.

The assumed configuration for the potential new E-W connection assumed is shown in Figure 17.

Traffic Volume Assumptions

With the implementation of a new E-W Connection it was assumed that some trips accessing the PRGS site would change their routes. For purposes of this analysis, approximately 50% of PRGS site trips using the following movements were assumed to shift to the new E-W Connection:

Slaters Lane

- Southbound left-turn from W Abingdon Drive to eastbound Slaters Lane
- Westbound right-turn from Slaters Lane to northbound E Abingdon Drive
- Westbound left-turn from Slaters Lane to southbound W Abingdon Drive

Bashford Lane

- Northbound right-turn from E Abingdon Drive to eastbound Bashford Lane
- Westbound right-turn from Bashford Lane to northbound GW Memorial Parkway
- Westbound left-turn from Bashford Lane to southbound GW Memorial Parkway

The assumed re-routes to traffic volumes for each of the above listed movements are shown in Figure 18.

Signal Timing Assumptions

The traffic signal phasing and timing schemes for the new E-W Connection intersections were assumed to largely mimic those at the Bashford Lane intersections due to their similarity in configuration. The assumed signal phasing is provided in Figure 19.

The following parameters were set equal to the values used at the Bashford Lane traffic signal:

- Minimum Green Time
- Yellow Time
- All-Red Time
- Recall Mode
- Pedestrian Walk Time
- Pedestrian Flash Don't Walk Time

The E-W Connection intersection was assumed to use the same cycle length as the Slaters Lane and Bashford Lane intersections in all alternatives. The signal timings were optimized based on the projected traffic volumes. Additionally, signal timings and offsets at the Slaters Lane and Bashford Lane intersections were optimized to account for the addition of the E-W Connection.

Overall Findings

When the conceptual alternatives were re-analyzed with the inclusion of the potential new E-W connection, it was found that the new connection may provide some minor advantages to vehicular throughput, delay, travel times, and queuing, particularly in the AM peak hour, with slight disadvantages in the PM peak hour.

The addition of a potential new E-W Connection allowed several alternatives to meet or exceed the percentage of vehicles processed under the 2033 Background scenario, as compared to the same alternatives without the connection. However, the overall increases were minimal: approximately 4% in the AM peak hour and 2% in the PM peak hour. Furthermore, improvements were not the same across the study area or between peak hours. In the AM peak hour, the greatest improvement in vehicle throughput was observed northbound on the GW Memorial Parkway, whereas minimal improvement was observed for eastbound vehicles on Slaters Lane. In the PM peak hour, minor improvements to vehicular throughput were observed southbound on the GW Memorial Parkway with no notable improvements elsewhere in the network. Total vehicular delay at study intersections decreased in the AM peak hour with the introduction of the new E-W Connection. However, the results for the PM peak hour were mixed. In roughly half of the analyzed alternatives, the total delay increased in the PM peak hour once the connection was added, with reductions in delays in the remaining alternatives.

The travel time results generally mirror the vehicular delay results. In the AM peak hour, there was an overall reduction in average travel times with the addition of the new connection. In the PM peak hour, there was an overall reduction in average travel times in roughly half of the analyzed alternatives, with increases in travel times in the remaining alternatives.

Maximum queue lengths results were mixed, with queue lengths generally decreasing in roughly half of the analyzed alternatives in both the AM and PM peak hours. The new E-W connection adds flexibility in route choice for drivers entering/exiting the PRGS site; however, reductions in queue lengths for one approach is offset by an increase in queue lengths for another approach where the vehicles have shifted.

Further detail regarding each of the listed MOEs is included in the Analysis Results section below.

This potential connection would require the cooperation and coordination of NPS and other property owners.

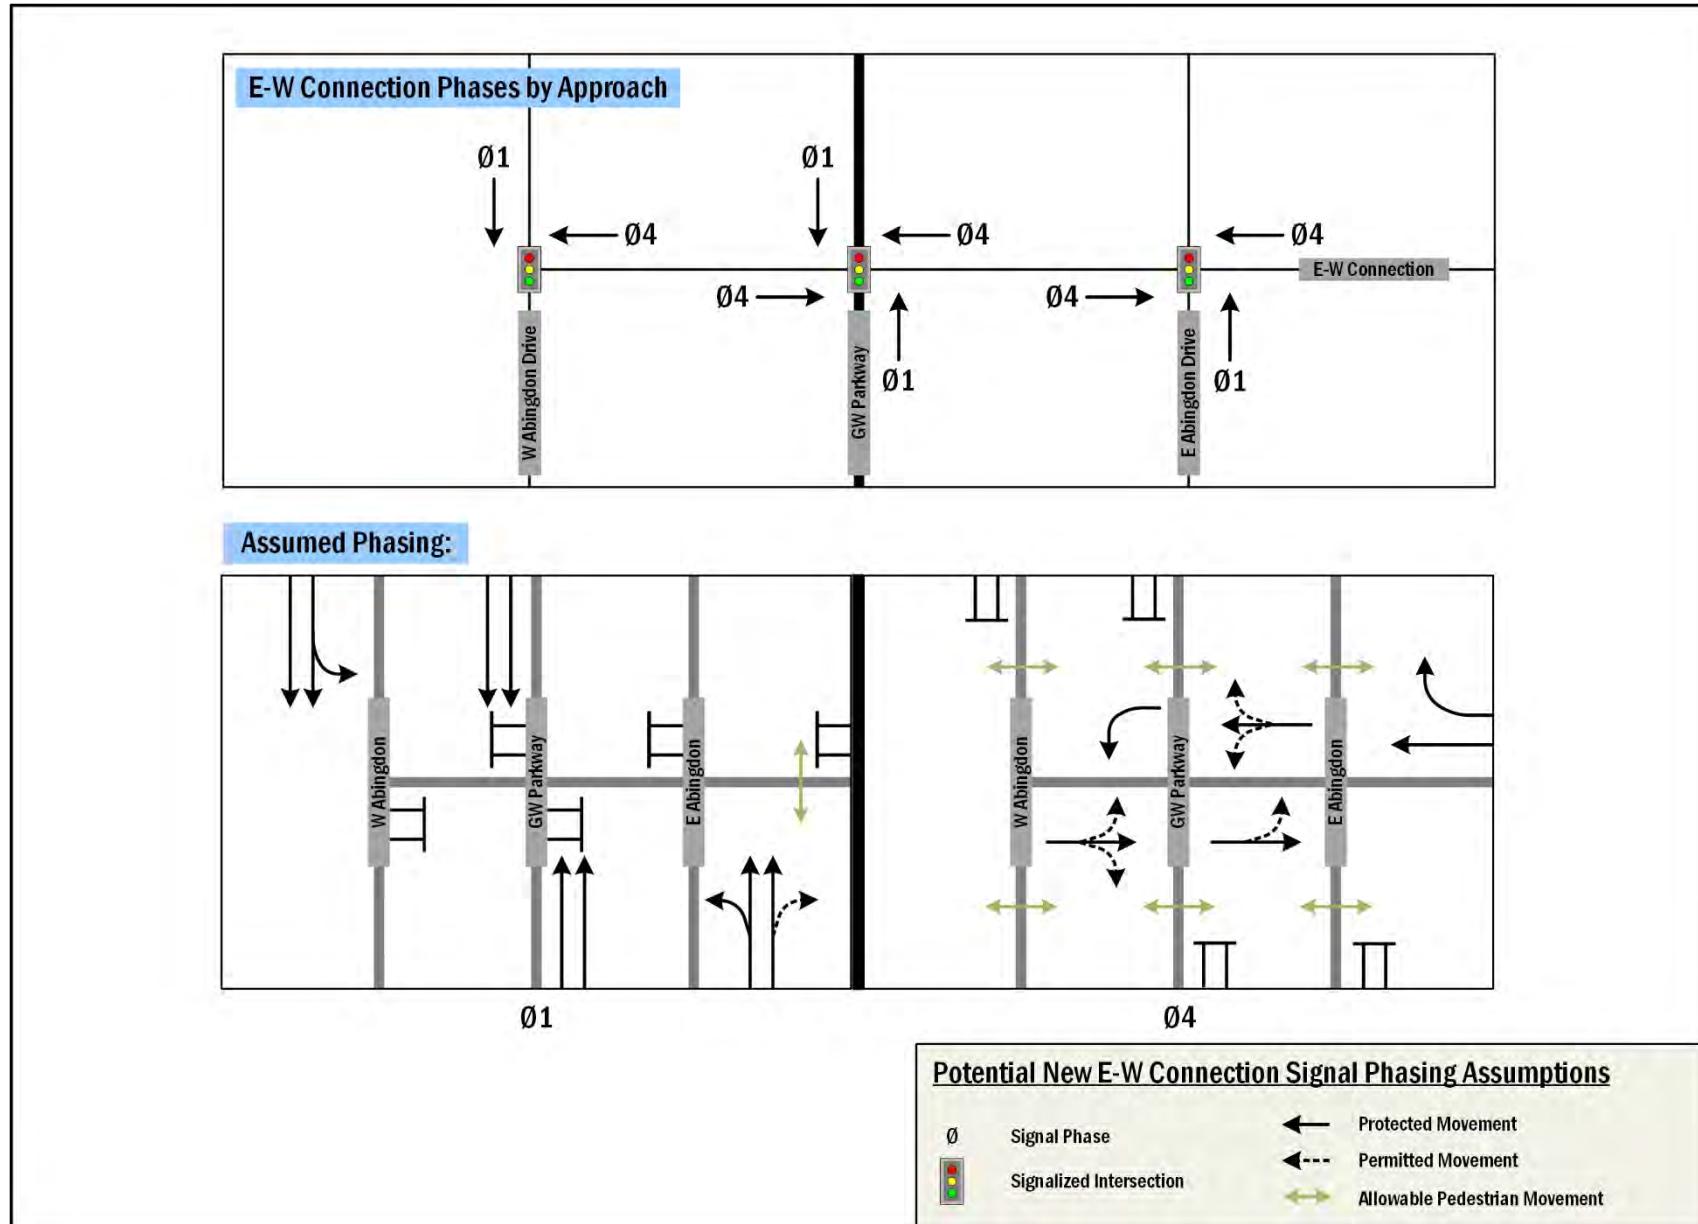

Figure 19: Potential New E-W Connection Signal Phasing Assumptions

2033 Future VISSIM Analysis Results (With the Potential E-W Connection)

All 12 conceptual alternatives were analyzed with and without the potential new E-W Connection using microsimulation (VISSIM) software to evaluate the impacts due to the addition. The Measures of Effectiveness (MOEs) used to evaluate the VISSIM results were the same as those used in the context of alternatives without the E-W Connection, including:

- **Vehicular Volumes:** This metric is used to help identify each alternative's ability to process volumes through the network, thus identifying issues relating to capacity.
- **Vehicular Delay:** This metric calculates the time spent by each vehicle in the network traveling below their desired speed.
- **Simulated Vehicular Travel Times:** This metric measures the time it takes a vehicle, on average, to traverse a given segment of the network.
- **Maximum queue Lengths:** This metric evaluates the maximum queue lengths observed on approaches to study intersections.

Detailed MOE tables for each alternative are provided in the Technical Attachments. VISSIM is a vehicular-focused software and the MOEs used to evaluate each alternative focus on the optimization of vehicular operations, rather than evaluating the positive and/or negative impacts to non-auto modes. It is important that each potential improvement weigh both the findings of this analysis and non-auto considerations to ensure that improvements are implemented from a multimodal standpoint.

Vehicular Volumes

Vehicular volume results are used to help identify each alternatives' ability to process vehicular volumes on a macro and micro level. These results are expressed as the number of vehicles processed into network. Individual link vehicular volume throughput at each study intersection is provided in the Technical Attachments.

The number of vehicles processed at network entry points system-wide are presented for all alternatives, with and without the potential new connection, are summarized in Table 16 for the AM and PM peak hours. The percentage of vehicles processed compared to the input vehicles for the peak hour is also included for each alternative.

The analysis results show that the addition of a potential new E-W Connection allowed several alternatives to meet or exceed the percentage of vehicles processed under the 2033 Background scenario, as compared to the same alternatives without the connection. However, the average increase in vehicles processed was relatively minor with approximately 4% in the AM peak hour and 2% in the PM peak hour. The greatest increase in percentage of vehicles processed was seen in alternatives with the lowest vehicles processed without the new connection (e.g., Alternatives 2 and 5A). Furthermore, improvements were not the same across the study area or between peak hours. In the AM peak hour, the greatest improvement in vehicle throughput was observed northbound on the GW Memorial Parkway, whereas minimal improvement was observed for eastbound vehicles on Slatters Lane. In the PM peak hour, minor improvements to vehicular throughput were observed southbound on the GW Memorial Parkway with no notable improvements elsewhere in the network.

Of the three (3) preferred alternatives identified in the previous analysis without the new connection, all showed a slight increase in vehicles processed with the E-W Connection in the AM and PM peak hours. This potential connection would require the cooperation and coordination of NPS and other property owners.

Table 16: Number of Vehicles Processed into Network (E-W Connection Comparison)

Alternative		AM Peak Hour		PM Peak Hour	
		Vehicles Processed (veh/hr)	Vehicles Processed as a Percentage of Input Vehicles (%)	Vehicles Processed (veh/hr)	Vehicles Processed as a Percentage of Input Vehicles (%)

2033 Future Alternative 8	w/o Connection	5,052	87%	6,056	90%
	w/ Connection	5,599	96%	6,069	90%
2033 Future Alternative 9	w/o Connection	5,671	97%	6,198	92%
	w/ Connection	5,703	98%	6,299	94%

Vehicular Delays

Simulated vehicular delay results show the difference between the actual vehicle travel time due to stops at a signalized intersection (control delay) and is measured in seconds of delay per vehicle.

It is important to note that VISSIM is a microscopic analysis rather than a macroscopic analysis. The improvements are in place to address targeted issues at specific locations, as well as increase the vehicular throughput of the overall network. Due to the increased number of vehicles being processed in the network compared to 2033 Background conditions, there may be locations where delays are higher than that seen under 2022 Existing and/or 2033 Background conditions for some locations.

AM Peak Hour

To provide a simple comparison of the delay experienced by drivers with the new signalized connection, Table 17 shows the total vehicular delays (in seconds per vehicle) for the study area for the AM peak hour. The total vehicular delay for alternatives without the new E-W Connection show the sum overall intersection delays for the intersections at Slaters Lane and Bashford Lane only (as shown in Table 6). The total vehicular delay for alternatives with the new E-W Connection show the sum of overall intersection delays for the intersections at Slaters Lane and Bashford Lane, as well as the new E-W Connection. The detailed vehicular delay results, including individual intersection and approach delays, are included in the Technical Attachments.

Overall, the vehicular delay results show that delays decreased in the AM peak hour for each alternative with the addition of the new connection, compared to the same alternative without the new connection.

Of the three (3) preferred alternatives identified in the previous analysis without the new connection, all showed a reduction in total delay with the E-W Connection in the AM peak hour.

PM Peak Hour

To provide a simple comparison of the delay experienced by drivers with the new signalized connection, Table 17 shows the total vehicular delays (in seconds per vehicle) for the study area for the PM peak hour. The total vehicular delay for alternatives without the new E-W Connection show the sum overall intersection delays for the intersections at Slaters Lane and Bashford Lane only (as shown in Table 9). The total vehicular delay for alternatives with the new E-W Connection show the sum of overall intersection delays for the intersections at Slaters Lane and Bashford Lane, as well as the new E-W Connection. The detailed vehicular delay results, including individual intersection and approach delays, are included in the Technical Attachments.

The vehicular delay results show mixed results for the PM peak hour. In roughly half of the analyzed alternatives (MTS Baseline and Alternatives 1, 2, 4, 8, and 9), the total delay increased in the PM peak hour once the connection was added, with reductions in delays in the remaining alternatives.

Of the three (3) preferred alternatives identified in the previous analysis without the new connection, Alternatives 6 and 7B showed a reduction in total delay with the E-W Connection in the PM peak hour. Alternative 9 showed a slight increase in vehicular delays.

Table 17: AM and PM Peak Hour Total Vehicular Delay Results (E-W Connection Comparison)

	w/ Connection	115.8

Simulated Vehicular Travel Times

Vehicular travel time is the amount of time it takes for a vehicle to travel from point A to point B. It is a direct reflection of motorist experience. Therefore, it is a critical and effective measure when evaluating and comparing the conceptual alternatives. The same four (4) travel time segments (shown in Figure 16) were analyzed as part of the analysis with the potential new connection, including:

- Northbound GW Memorial Parkway north of Bashford Lane to north of Slaters Lane
- Southbound GW Memorial Parkway south of Slaters Lane to south of Bashford Lane
- Northbound E Abingdon Drive north of Bashford Lane to north of Slaters Lane
- Southbound W Abingdon Drive south of Slaters Lane to south of Bashford Lane

Because the E-W Connection would be located between Slaters Lane and Bashford Lane, the travel time measurements for scenarios with the connection reflect the impact of the additional intersection on driver experience in the study area.

AM Peak Hour

Simulated travel time results for the four (4) vehicular travel time measurement segments that were analyzed using VISSIM in for each conceptual alternative, with and without the new connection, are shown in Table 18 for the AM peak hour. The travel time results are reported in terms of the average travel time for each segment, as well as a volume-weighted average travel time across all four (4) segments for an overall comparison.

The travel times results for most alternatives are lower or comparable to that reported for the same alternative without the new connection during the AM peak hour. That being said, the average decrease in travel time across all segments was only approximately nine (9) seconds. Of the three (3) preferred alternatives identified in the previous analysis without the new connection, all showed an overall reduction in travel times with the E-W Connection in the AM peak hour.

PM Peak Hour

Simulated travel time results for the four (4) vehicular travel time measurement segments that were analyzed using VISSIM in for each conceptual alternative, with and without the new connection, are shown in Table 19 for the PM peak hour. The travel time results are reported in terms of the average travel time for each segment, as well as a volume-weighted average travel time across all four (4) segments for an overall comparison.

In the PM peak hour, there was an overall reduction in average travel times in roughly half of the analyzed alternatives, with increases in travel times in the remaining alternatives. Among those alternatives where a reduction was observed, the average decrease in travel time across all segments was only approximately three (3) seconds. Of the three (3) preferred alternatives identified in the previous analysis without the new connection, Alternatives 6 and 7B showed an overall reduction in travel times with the E-W Connection in the PM peak hour. Alternative 9 showed an increase in overall travel times.

Maximum Queue Length

The maximum queue length is the maximum observed distance from the stop bar to the back of queue or to the next upstream study intersection.

AM Peak Hour

The average maximum queue length for five (5) simulation runs at each approach of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection, with and without the new connection, is shown in Table 20 for the AM peak hour. The average maximum queue length for five (5) simulation runs at each approach of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection, with and without the new connection, is shown in Table 21 for the AM peak hour.

The maximum queue lengths for all approaches of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the AM peak hour, with and without the new E-W Connection. The greatest variability is observed on the southbound approach on W Abingdon Drive. The introduction of the E-W Connection provides an additional route choice to the PRGS site for vehicles which would otherwise make a southbound left turn from W Abingdon Drive to Slaters Lane. The added flexibility results in fewer vehicles queuing to make the southbound left-turn movement at Slaters Lane as a portion of vehicles shift to the new connection.

The maximum queue lengths for all approaches of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the AM peak hour, with and without the new E-W Connection. For the northbound approach on the GW Memorial Parkway, a reduction in maximum queue was observed in nine (9) of the 12 alternatives, but with varying magnitudes. In most alternatives, there was an increase in the maximum queue length for the eastbound and westbound approaches on Bashford Lane. In most alternatives, a reduction in queue lengths for the northbound approach was offset by an increase in queue lengths on the Bashford Lane approaches as volumes shift due to the new connection. Of the three (3) preferred alternatives identified in the previous analysis without the new connection, this tradeoff was shown in Alternative 7B, but not Alternative 6 or 9.

PM Peak Hour

The average maximum queue length for five (5) simulation runs at each approach of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection, with and without the new connection, is shown in Table 22 for the PM peak hour. The average maximum queue length for five (5) simulation runs at each approach of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection, with and without the new connection, is shown in Table 23 for the PM peak hour.

The maximum queue lengths for some approaches of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the PM peak hour, with and without the new E-W Connection. For the northbound approach on the GW Memorial Parkway, a reduction in maximum queue length was shown in all 12 alternatives, but with varying magnitudes. In some alternatives, there was an increase in the maximum queue length for the southbound approach on W Abingdon Drive. In general, a reduction in queue lengths for the northbound approach was offset by an increase in queue lengths on the W Abingdon Drive approach in alternatives where the cycle length was not increased (MTS Baseline and Alternatives 1, 2, 4, 5A, 5B, 6, and 8). Of the three (3) preferred alternatives identified in the previous analysis without the new connection, this tradeoff was not present in the results of Alternative 7B or 9.

The maximum queue lengths for all approaches of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the PM peak hour, with and without the new E-W Connection.

Conclusions and Recommendations

This memorandum presented the findings of a microsimulation (VISSIM) traffic analysis for the proposed redevelopment of the Potomac River Generating Station (PRGS) site. The purpose of this memorandum was to present the findings of microsimulation (VISSIM) analysis that evaluate numerous conceptual alternatives for the intersections of Slaters Lane and Bashford Lane with the GW Memorial Parkway aimed at ameliorating the traffic impacts to vehicular modes generated by the proposed site, with the goal of identifying preferred alternatives which will be further studied as part of the Feasibility Study described in the project's Coordinated Development District (CDD) Condition 37.

Twelve (12) conceptual alternatives were analyzed as part of this memorandum. The conceptual alternatives include baseline mitigations identified as part of the PRGS CDD MTS, improvements identified by the City for exploration, and additional improvements identified by Gorove Slade throughout the conceptual alternative development and analysis. Of the viable alternatives, three (3) alternatives are preferred and recommended for future study. Each preferred alternative processed levels of traffic comparable to that processed under 2033 Background conditions in the AM and PM peak hours, while minimizing impacts to vehicular delay, queues, and travel times. Each alternative performed better than other alternatives in at least vehicular delays, vehicular travel times, or maximum queue lengths.

VISSIM is a vehicular-focused software and the metrics used to evaluate each alternative focus on the optimization of vehicular operations, rather than evaluating the positive and/or negative impacts to non-auto modes. It is important that each potential improvement weigh both the findings of this analysis and non-auto considerations to ensure that improvements are implemented from a multimodal standpoint.

The improvements of each preferred alternative are included below:

- **Alternative 6:**
 - Additional eastbound receiving lane on Bashford Lane
 - Added southbound right-turn lane on W Abingdon Drive at Slaters Lane
 - Lane configuration modifications on Bashford Lane
 - Turn restrictions at the Slaters Lane and Bashford Lane intersections to consolidate turning movements
 - Phasing modifications at Slaters Lane
 - Extend two lanes of storage on W Abingdon Drive between Slaters Lane and GW Memorial Parkway
 - Modified cycle length of the Slaters Lane and Bashford Lane intersections
- **Alternative 7B:**
 - Additional eastbound receiving lane on Bashford Lane
 - Lane configuration modifications on Bashford Lane
 - Turn restrictions at Slaters Lane and Bashford Lane intersections to consolidate turning movements
 - Phasing modifications at Slaters Lane
 - Southbound left-turn lane on W Abingdon Drive at Slaters Lane
 - Extend two lanes of storage on W Abingdon Drive between Slaters Lane and GW Memorial Parkway
 - Modified cycle length of the Slaters Lane and Bashford Lane intersections

- **Alternative 9:**

- Additional eastbound receiving lane on Bashford Lane
- Lane configuration modifications on Bashford Lane
- Turn restrictions at Slaters Lane and Bashford Lane intersections to consolidate turning movements
- Phasing modifications at Slaters Lane
- Added southbound left-turn lane on W Abingdon Drive at Slaters Lane
- Extend two lanes of storage on W Abingdon Drive between Slaters Lane and GW Memorial Parkway
- Modified cycle length of the Slaters Lane and Bashford Lane intersections
- Modified traffic signal timings at Slaters Lane and Bashford Lane to optimize eastbound and westbound movements and reduce conflict between turning vehicles and pedestrians

From a vehicular standpoint, the results indicate that Alternatives 6, 7B, and 9 would result in the greatest operational improvements by prioritizing the number of vehicles processed by the analysis network, while minimizing impacts to vehicular delay, queues, and travel times. Each of these preferred alternatives are able to process at least the same percentage of vehicles as was processed in the 2033 Background scenario during both the AM and PM peak hours. Each preferred alternative also performed better than the other analyzed alternatives in at least one of the other MOEs of vehicular delays, vehicular travel times, and vehicular queues. It is important that each potential improvement weigh both the findings of this analysis and non-auto considerations to ensure that improvements are implemented from a multimodal standpoint.

This memorandum recommends that the preferred alternatives identified as part of this analysis (Alternatives 6, 7B, and 9) be studied further in the future as the PRGS site develops. The underlying assumptions for the trip generation for the PRGS redevelopment were based on a conservative development program, which is subject to change as part of future DSUPs and may result in fewer vehicular trips, and pre-COVID-19 pandemic data, and likely are not fully representative of current or future driver behavior and traveler decisions (e.g., remote work, dispersion of arrival trip patterns across peak periods). Additionally, the improvements identified based on this analysis would not be implemented until Phase 2 of the PRGS redevelopment, at which point assumptions could be refined with respect to the proposed development program and shifts in commuting patterns in the study area. The site trip generation calculations were based on the most conservative (60% commercial/40% residential) development option for the PRGS site, which is subject to change as development progresses.

When the preferred alternatives are re-analyzed with the inclusion of the potential new E-W connection, it was found that the new connection may provide some minor advantages to vehicular throughput, delay, travel times, and queuing, particularly in the AM peak hour, with slight disadvantages in the PM peak hour. The potential new E-W Connection will be further studied once future DSUPs are submitted in Phase 2. As part of this future study, the analysis should weigh the advantages and disadvantages of the new connection for non-vehicular modes against that for vehicles. Additional conclusions include:

- The introduction of the new E-W Connection resulted in minimal increases to the number of vehicles processed: approximately 4% in the AM peak hour and 2% in the PM peak hour.
- Overall, the vehicular delay results show that delays decreased in the AM peak hour for each alternative with the addition of the new connection, compared to the same alternative without the new connection. The vehicular delay results show mixed results for the PM peak hour. In roughly half of the analyzed alternatives (MTS Baseline and Alternatives 1, 2, 4, 8, and 9), the total delay increased in the PM peak hour once the connection was added, with reductions in delays in the remaining alternatives.

- The travel times results for most alternatives are lower or comparable to that reported for the same alternative without the new connection during the AM peak hour. In the PM peak hour, there was an overall reduction in average travel times in roughly half of the analyzed alternatives, with increases in travel times in the remaining alternatives.
- The maximum queue lengths for all approaches of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the AM peak hour, with and without the new E-W Connection. In most alternatives, there was an increase in the maximum queue length for the eastbound and westbound approaches on Bashford Lane. Additionally, a reduction in queue lengths for the northbound approach was offset by an increase in queue lengths on the Bashford Lane approaches as volumes shift due to the new connection. The maximum queue lengths for some approaches of the Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the PM peak hour, with and without the new E-W Connection. The maximum queue lengths for all approaches of the Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive intersection are similar across all analyzed alternatives in the PM peak hour, with and without the new E-W Connection.

As part of the future Phase 2 study, the analysis should weigh the advantages and disadvantages of the new connection for non-vehicular modes against that for vehicles.

Appendix E – VISSIM Analysis Results – Vehicular Travel Times

Appendix F – VISSIM Analysis Results – Vehicular Queues

A. VISSIM Analysis Scope

**Potomac River Generating Station (PRGS) Redevelopment
VISSIM Scoping**

1. The VISSIM model will be used to analyze the GW Memorial Parkway corridor, including the following signalized intersections:
 - 1) Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive
 - 2) Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive

Signalized intersections adjacent to the study intersections listed above will also be coded in the VISSIM models, as shown in Figure 1. These intersections will be used for network metering purposes only; as such, no results will be reported at these locations.
2. The VISSIM model will be built in compliance with City of Alexandria guidelines and existing network characteristics. VISSIM 11.00-14 will be used.
3. The seeding period and number of simulation runs will be determined based on City of Alexandria guidelines and existing network characteristics. The simulation results will be based on an average of five (5) simulation runs will be included for each scenario. Each model run will be seeded for a 1-hour period and followed by a 1-hour simulation period.
4. We propose collecting weekday turning movement counts (including pedestrians), travel time data, and back of queue observations during Spring 2022 between 6:30-9:30 AM and 4:00-7:00 PM for the intersections within the study area. We will conduct counts on a “typical weekday” when Alexandria public schools and Congress are in session. Efforts will be made to avoid conducting counts when there is inclement weather.
5. The existing (Year 2022) conditions VISSIM model will be established by coding the vehicle inputs and routing decisions using the newly collected peak hour traffic volumes, as well as other resources available to Gorove Slade. The VISSIM analysis will be conducted based on the vehicle fleet for North America.
6. As part of the existing model calibration process, the following measures of effectiveness (MOEs) will be utilized to compare the model outputs with the field data:
 - Vehicular volumes (throughputs) at signalized intersections
 - Vehicular travel times along coded measurement segments, including:
 - a. NB GW Memorial Parkway north of Bashford Lane to north of Slaters Lane
 - b. SB GW Memorial Parkway south of Slaters Lane to south of Bashford Lane
 - c. NB E Abingdon Drive north of Bashford Lane to north of Slaters Lane
 - d. SB W Abingdon Drive south of Slaters Lane to south of Bashford Lane
 - Maximum queue length at signalized intersections

The field data, including the field-measured travel times, queue observations, and traffic volumes, will be used to calibrate the existing conditions VISSIM model based on the City of Alexandria guidelines as shown below:

VISSIM Calibration Thresholds

Criteria and Measures	Calibration Acceptance Targets
Modeled Link Volume (vehicles per hour)	Within \pm 100 vph for < 700 vph Within \pm 15% for 700 vph to 2,700 vph Within \pm 400 vph for > 2,700 vph Within \pm 5% of sum of all link counts
Modeled Travel Time (seconds)	Within \pm 15% of observed travel times
Modeled Queue Length (feet)	Within \pm 30% of observed queue lengths

7. Based on the analysis results, the following MOEs will be reported for each signalized intersection:
 - 1) Vehicular Volumes
 - 2) Maximum Queue Length
 - 3) Intersection Delay
 - 4) Vehicular Travel Times along coded segments
8. A document including the calibration process and results will be submitted to the City of Alexandria for review prior to beginning work on the future conditions models. Adjustments to the calibrated existing conditions model will be made based on the City's review. The document will include the following elements:
 - Overview of the study area characteristics
 - Overview of the existing conditions VISSIM model
 - Calibration criteria, procedure, and results
 - Justification that the model is sufficiently calibrated
 - Justification of any deviation from the calibration criteria
9. The City of Alexandria will provide comments on the calibrated VISSIM model within three (3) weeks of submission. If needed, Gorove Slade will address any comments and resubmit the calibrated VISSIM model and accompanying document within a week of receiving comments from the City.
10. Once the calibrated existing conditions model has been accepted by the City's review, the existing conditions' MOEs will be documented, and the model will be updated to analyze future scenarios including:
 - Future without Development (Year 2033)
 - Future with Development (Year 2033)
 - Future with Development (Year 2033) - Mitigated
 - Future with Development (Year 2033) - Mitigated with East-West Connection

As part of the mitigated conditions, we will also explore the following improvements:

- Providing a dedicated left-turn lane on W Abingdon Drive and E Abingdon Drive (lead-lag phasing operation)
- Extension of the two (2) lanes on W Abingdon Drive between GW Memorial Parkway and Slaters Lane
- Changes to maximum cycle length at Slaters Lane, Bashford Lane, and new East-West Connection

-
11. Traffic demand forecasting for all analyzed scenarios will be based on the assumptions included in the PRGS MTS, including inherent regional growth rates, background developments, and any planned network improvements.

The PRGS MTS was based on the preferred development option proposed by the applicant, which includes a total of up to 2.5 million GSF of development with a mix of office, arts, retail, residential, and hotel uses. However, the program is subject to change and the exact program for each development block will be determined as part of future DSUPs.

12. A document including the modeling/calibration approach and VISSIM analysis results for the existing and future scenarios will be submitted to the City of Alexandria. The document will outline the following:
 - Previously mentioned items as part of the existing conditions VISSIM model development and calibration (see #8)
 - Overview of the future traffic patterns in the study area
 - Overview of the future demand development for different modes
 - The MOEs for the future scenarios
 - Description of any modification to the future traffic network including the improvements outlined in PRGS CDD MTS as well as required improvements based on the microsimulation analysis
13. The City of Alexandria will provide comments within four (4) weeks of final document submission. The model and corresponding documents will be adjusted as needed and will be finalized based on the City's review.

B. VISSIM Calibration Memorandum (August 2022)

TECHNICAL MEMORANDUM

To: Ryan Knight, P.E. City of Alexandria

From: Sasha Redmon
Adam Nodjomian, P.E.
Niraja Chandrapu, P.E., PTOE
Daniel Solomon, AICP
Daniel B. VanPelt, P.E., PTOE

Date: July 25, 2022 (revised August 19, 2022)

Subject: Potomac River Generating Station – VISSIM Model Calibration

The following memorandum outlines the assumptions and calibration parameters used to develop the VISSIM network for the Potomac River Generating Station (PRGS) Redevelopment in Alexandria, VA. Attached to this memorandum are copies of the calibrated VISSIM network files and the Measures of Effectiveness (MOEs). Per the agreed upon scope with the City, we are requesting that the City review the attached documents and provide feedback on the calibrated VISSIM network prior to development of the networks for future conditions. This memorandum has been revised to address comments from the City of Alexandria. Additional clarification was added to the discussion of model calibration. Namely, the reasoning for adjusting lane change distances and driver behaviors within the models was expanded. Also, further background on the inclusion of high occupancy vehicle (HOV) lanes within the models and routing of unmet demand were added to the memorandum.

Study Area Overview

The PRGS site is located in the Old Town North area of Alexandria, VA and is bounded by Slaters Lane to the north, E Abingdon Drive to the west, Norfolk Southern Corporation right-of-way to the south, and the Potomac River to the east. The study area of the analysis is the set of intersections where detailed capacity analyses will be performed for future scenarios. The following intersections were identified for inclusion in the existing VISSIM network, as shown in Figure 1. Additional intersections were included in the existing network for metering purposes and results will not be reported for these locations.

1. Slaters Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive
2. Bashford Lane and GW Memorial Parkway/E Abingdon Drive/W Abingdon Drive

The set of intersections included are those intersections on GW Memorial Parkway most likely to have potential impacts or require changes to traffic operations to accommodate the PRGS Redevelopment. The scope of analysis was extensively discussed with and approved by the City.

Figure 1: Existing Study Area

Simulation Model Development

Grove Slade used the existing geometry and turning movement volumes to create a VISSIM model that represents current operating conditions. The summary of VISSIM network inputs used for the existing model development is as follows:

- Roadway Geometry and Operations – Grove Slade conducted field reviews to verify the current roadway geometry and operations, including the intersection lane configurations, storage lengths, and signal phasing, to match the current field conditions;
- Link Speed Distribution – The inputs for desired speed decisions were verified based on the posted speed limits along the corridor. Desired speed decisions were updated, where appropriate, during the calibration process, as noted in the Model Calibration section. The inputs for reduced speed areas for left turns and right turns were reviewed to be consistent with City of Alexandria and Virginia Department of Transportation (VDOT) guidelines;
- Traffic Volumes – In order to establish a calibrated model, turning movement volumes were used to develop a balanced network using system peak data during AM and PM peak periods. The AM system peak period is from 7:45AM to 8:45 AM and the PM system peak period is from 5:00PM to 6:00PM;
- Transit – DASH Line 34 travels through the study area and was therefore included in the model. Boarding and alighting data were provided by the City of Alexandria for the northbound and southbound routes of the line and are included in the Technical Appendix;
- Vehicle Composition – The North America vehicle fleet was used;
- Simulation Duration – Overall simulation duration was set to two (2) hours. Each model run is seeded for a 1-hour period and followed by a 1-hour analysis/recording period;
- Number of Simulation Runs – Ten (10) simulation runs were performed for the AM and PM peak periods, in accordance with City of Alexandria and VDOT guidelines;
- Simulation Resolution – The simulation results are based on a simulation resolution of ten (10) time steps per simulation second;
- Simulation Speed – The simulation results are based on a simulation speed of ten (10) simulation seconds per second; and
- Driver Behavior – Driver behavior parameters were updated, where appropriate, during the calibration process as noted in the Model Calibration section.

Model Calibration

Model calibration is the process of performing adjustments to the model to better simulate local driving behavior and operational performance. The calibration process typically compares field data (volumes, speed, travel time, queue length, etc.) to the simulation output so that the model represents actual traffic conditions in the study area. A model that is appropriately calibrated improves the model's ability to assess the future conditions of the study area. The calibration criteria were scoped and approved by the City. All reasonable efforts were made to calibrate the VISSIM models to the calibration criteria and targets. Travel time field measurements were conducted along both directions of GW Memorial Parkway, between Slaters Lane and Bashford Lane. The existing peak hour traffic volumes and travel time field measurements are attached.

Some model parameters were adjusted to reflect actual network performance and driver behaviors. The models were run with adjusted parameters and the outputs were examined against field measurements. To validate and calibrate the model, the driver behavior parameters were changed from their default values to the values defined in Table 1 during the AM and PM analysis.

Note that the new driver behavior parameters were applied on case-by-case basis to some of the model links to better replicate the drivers' lane change behavior and typical speed distribution. Lane change distances and driver behavior were modified on those links where, during initial stages of model calibration, simulated vehicles would not be in the proper lane to make a turning

maneuver before a decision point. Speed distributions were modified on those links where, during initial stages of model calibration, simulated travel times were not indicative of observed travel times under existing conditions. The locations with modifications, and the peak hour(s) which they apply to are as follows:

- SB input on GW Memorial Parkway:
 - o Vehicles which are present within the network under existing conditions but did not reach an intersection by the end of the data collection period, are not reflected in the collected traffic counts. To simulate the vehicles not captured in the turning movement traffic counts, an additional input was added to the northernmost link in the network to better represent existing conditions. Further detail of this modification is included in the subsequent section.
- NB approach of the E Abingdon Drive and Slaters Lane intersection:
 - o Modified lane change distance for the right-turn movement from the default of 656.2 feet to 1200 feet to give simulated vehicles more time to reach the proper lane (AM & PM).
- EB approach of the W Abingdon Drive and Slaters Lane intersection:
 - o Modified lane change distance for the right-turn and through movements from the default of 656.2 feet to 1200 feet to give simulated vehicles more time to reach the proper lane (AM & PM).
 - o Modified EB link from the default “urban (motorized)” driver behavior to the “urban (aggressive)” driver behavior to more accurately represent acceptable gaps sought by drivers when attempting to reach the proper lane and the cooperation between drivers to reach the proper lane at decision points (PM).
- EB volume balancing location between W Abingdon Drive and Portner Road/Potomac Greens Drive:
 - o Modified lane change distance for the right-turn movement from the default of 656.2 feet to 1200 feet to give simulated vehicles more time to reach the proper lane (AM & PM).
- E Abingdon Drive between the south and north ramps:
 - o Modified desired speed decision to 30 miles per hour (MPH) from the posted speed limit of 25 MPH to better align with observed vehicle speeds on that roadway (AM & PM)
- W Abingdon Drive between Slaters Lane and Bashford Lane:
 - o Created an area with reduced speed decisions to replicate speed reductions caused by adjacent parking spaces near the midpoint of the link (AM).
- GW Memorial Parkway between Bashford Lane and First Street:
 - o Modified desired speed decision to 25 miles per hour (MPH) from the posted speed limit of 30 MPH to better align with observed vehicle speeds on that segment (AM & PM).
- NB approach to the E Abingdon Drive ramp
 - o Modified lane change distance for the right-turn and through movements from the default of 656.2 feet to 1200 feet to give simulated vehicles more time to reach the proper lane (AM & PM).
- NB GW Memorial Parkway between the E Abingdon Drive ramp and First Street:
 - o Modified from the default “urban (motorized)” driver behavior to the “urban (aggressive)” driver behavior to more accurately represent acceptable gaps sought by drivers when attempting to reach the proper lane and the cooperation between drivers to reach the proper lane at decision points (AM & PM).
- GW Memorial Parkway south of First Street:
 - o Modified SB desired speed decision to 15 mile per hour (MPH) from the posted speed limit of 25 MPH to replicate downstream congestion and traffic signals (AM & PM).

- Modified NB link from the default “urban (motorized)” driver behavior to the “urban (aggressive)” driver behavior to more accurately represent acceptable gaps sought by drivers when attempting to reach the proper lane and the cooperation between drivers to reach the proper lane at decision points (AM & PM).

HOV Lanes

High occupancy vehicle (HOV) lanes were observed northbound on E Abingdon Drive and southbound on W Abingdon Drive. Inclusion of these lanes into the PRGS VISSIM model were considered, however, based on field observations, the restriction is largely ignored by motorists. Therefore, to be more representative of existing conditions, HOV lanes were omitted from the model.

Southbound Queuing on GW Memorial Parkway

An important component of model calibration is aligning simulated and observed vehicular queues within the study area. This section summarizes modifications made to model parameters to ensure travel patterns in the VISSIM model were more representative of those observed in the field.

As a result of using collected intersection turning movement traffic counts to develop volumes for the model, vehicles which are present within the network under existing conditions but did pass through an intersection by the end of the data collection period, are not reflected in the counts, and therefore not reflected in the model.

In the case of southbound traffic on GW Memorial Parkway, maximum queues observed in the field reach approximately the Four Mile Run bridge (1.3 miles to the north) in the PM peak hour. Initial runs of the VISSIM model using only turning movement traffic counts as the basis for vehicle inputs, generated significantly shorter queues of approximately 0.25 miles. This indicated that an input volume based solely on the number of vehicles reaching the study intersections would not comprehensively capture actual demand on the GW Memorial Parkway.

To simulate the vehicles not captured in the turning movement traffic counts, an additional input was added to the northernmost link in the network. The number of vehicles generated by this input was determined by comparing the observed maximum queue length to the queue length determined by an initial run of the VISSIM model with no modifications to traffic volumes. The difference in maximum queue lengths was then converted to an approximately equivalent number of vehicles based on an average 25-foot headway. The equivalent number of vehicles were then added to the simulation.

Because turning movement data could not be collected for the unmet demand on southbound GW Memorial Parkway, the distribution of turning maneuvers was unknown. If the additional volume were to be added according to the collected distribution, impacts would be observed in the volume processed at downstream intersections, thus resulting in an uncalibrated model. Therefore, additional volume which was added southbound on the GW Memorial Parkway was assumed to continue straight through the network.

The resulting travel patterns were more representative of the observed existing conditions, while still aligning with traffic volume calibration requirements.

Driving Behaviors

Default values for driving behaviors were largely used for each of the three (3) driving behaviors present in the model. The “urban (aggressive)” driving behavior was applied to those links listed previously in the Model Calibration section to better align lane change behavior with that observed in the field near major decision points.

Given the absence of traffic signals north of the project area, the roadway operates similarly to a freeway facility with limited access points and ramp connections. As a result, the “freeway (free lane selection)” driving behavior was applied to all links on GW Memorial Parkway north of Slatters Lane.

All other links were assigned the “urban (motorized) driving behavior”.

The parameters for all three driving behaviors employed in the model can be found in Table 1, Table 2, and Table 3 below. Included in the tables are comparisons to default and recommended values.

Table 1: Driving Behavior Parameters – Urban (motorized) Driving Behavior

Car Following and Lane Change Parameters	Default	Suggested Range ¹	Used in Analysis
Average Standstill Distance	6.56 ft	3.28 to 6.56 ft	6.56 ft
Additive Part of Safety Distance	2.0	2.0 to 2.2	2.0
Multiplic. Part of Safety Distance	3.0	2.8 to 3.3	3.0

Calibration Criteria

Table 4 shows the summary of the VISSIM modeling calibration criteria and results. The VISSIM modeling calibration used in this analysis met the calibration acceptance targets in 100% of cases with respect to volume and travel time during the AM peak hour simulation and in approximately 96% of volume-based cases and 100% of travel time cases in the PM peak hour simulation. Calibration criteria for queueing were met for approximately 92% of cases in the AM and PM peak hours. City of Alexandria guidance states that calibration targets should be met in 100% of cases. Details for those movements where queue criteria were not met are discussed below Table 4. No vehicles were denied entry in any of the AM or PM simulation runs. Detailed calibration results are attached.

It should be noted that TOSAM guidance specifies a calibration target of 85% of cases for volume, travel time, and queue length parameters. Therefore, while calibration targets were not met in 100% of cases, all criteria were within the industry-accepted 85% range. Additionally, TOSAM states that maximum queue lengths should be calibrated using visual inspection and should prioritize “critical locations”. As a result, while queue length targets were not met in all cases, specific attention was given to major movements in the network and were compared visually to maximum queue lengths observed in the field.

Table 4: VISSIM Modeling Calibration Criteria and Results

Calibration Criterion ¹	Calibration Target ^{1,2}	Results	
		AM Peak	PM Peak
Modeled Link Volume (vehicles per hour)			
Within \pm 100 vph for < 700 vph			
Within \pm 15% for 700 vph to 2,700 vph	100% of cases	100%	95.8%
Within \pm 400 vph for > 2,700 vph			
Within \pm 5% of sum of all link counts	\pm 5%	- 1%	+ 9%
Modeled Travel Time (seconds)			
Within \pm 15% of Observed Travel Times	100% of cases	100%	100%
Simulated Queue Length			
Within \pm 30% of observed queue lengths	100% of cases	91.7%	91.7%

1. Based on City of Alexandria Transportation Planning Administrative Guidelines (June 2017)

2. VDOT TOSAM (2020) identifies calibration target of 85%

The following movements did not meet simulated queue length calibration targets in the AM peak hour:

- GW Memorial Parkway Southbound Through at Slaters Lane:
 - o No signalized intersections are present north of this approach. Therefore, traffic is not metered, and the simulation arrival patterns to the intersection cannot exactly replicate existing conditions.

The following movements did not meet simulated calibration targets in the PM peak hour:

- GW Memorial Parkway Southbound Through at Slaters Lane:
 - o As noted previously, the southbound queue on GW Memorial Parkway reaches a maximum length of approximately 1.3 miles. The simulated queue length was extended using the secondary volume addition discussed above. As a result, additional traffic volume traveled through the intersection resulting in the volume calibration target not being met.
- GW Memorial Parkway Southbound Through at Bashford Lane:
 - o As a result of the volume modifications at the north end of the network, additional traffic volume reaches the intersection resulting in longer queues than those observed in the field. For the same reason, the traffic volume calibration target was not met.

Calibration Results

The calibration and MOE results for the AM peak period are detailed in

Table 5, Table 6, and Table 7 for intersection volumes and delay, travel time measurements, and maximum queue lengths, respectively. The calibration and MOE results for the PM peak period are detailed in Table 8, Table 9, and Table 10 for intersection volumes and delay, travel time measurements, and maximum queue lengths, respectively.

All reasonable efforts were made as part of an iterative process to calibrate the VISSIM models to the calibration criteria and targets. The resulting models meet or exceed state and industry standards and meet or exceed calibration results from previous modeling efforts as part of the Old Town North Small Area Plan.
